The Condition
A ventral hernia is a bulge through an opening in the muscles on the abdomen. The hernia can occur at a past incision site (incisional), above the navel (epigastric), or other weak muscle sites (primary abdominal).

Common Symptoms
- Visible bulge on the abdomen, especially with coughing or straining
- Pain or pressure at the hernia site

Nonsurgical Procedure
Watchful waiting is an option for adults with hernias that are reducible and not uncomfortable.¹

Benefits and Risks of Your Operation
Benefits—An operation is the only way to repair a hernia. You can return to your normal activities and, in most cases, will not have further discomfort.

Risks of not having an operation—The size of your hernia and the pain it causes can increase. If your intestine becomes trapped in the hernia pouch, you will have sudden pain and vomiting and require an immediate operation.

If you decide to have the operation, possible risks include return of the hernia; infection; injury to the bladder, blood vessels, or intestines; and continued pain at the hernia site.

Surgical Procedure

Open hernia repair (OVHR)—An incision is made near the site, and the hernia is repaired with mesh or by suturing (sewing) the muscle closed.

Laparoscopic hernia repair (LVHR)—The hernia is repaired by mesh or sutures inserted through instruments placed into small incisions in the abdomen.

Expectations
Before your operation—Evaluation may include blood work, urinalysis, ultrasound, or a CT scan. Your surgeon and anesthesia provider will review your health history, home medications, and pain control options.

The day of your operation—You will not eat or drink for 4 hours before the operation. Most often, you will take your home medication with a sip of water. You will need someone to drive you home.

Your recovery—You may go home within 24 hours for small hernia procedures but may need to stay in the hospital longer for more complex repairs. The average length of stay for patients with a complex hernia repair is 1.5 days.²

Call your surgeon if you have severe pain, stomach cramping, chills with a high fever (higher than 101°F), odor or increased drainage from your incision, or no bowel movement for 3 days.

Work and Return to School
- After recovery, you can usually return to work or school within 2 to 3 days.
- You will not be able to lift anything over 10 pounds, climb, or do strenuous activity for 4 to 6 weeks following ventral hernia repair.
- Lifting limitation may last for 6 months for complex or recurrent repairs.

Call your surgeon if you have severe pain, stomach cramping, chills with a high fever (higher than 101°F), odor or increased drainage from your incision, or no bowel movement for 3 days.

Work and Return to School
- After recovery, you can usually return to work or school within 2 to 3 days.
- You will not be able to lift anything over 10 pounds, climb, or do strenuous activity for 4 to 6 weeks following ventral hernia repair.
- Lifting limitation may last for 6 months for complex or recurrent repairs.

Surgical Patient Education Program
Prepare for the Best Recovery

This first page is an overview. For more detailed information, review the entire document.
The Condition

The Hernia

A ventral hernia occurs when there is a weakness or hole in the muscles of the abdomen and a loop of intestine or abdominal tissue pushes through the muscle layer. If the hernia reduces in size when a person is lying flat or in response to manual pressure, it is reducible. If it cannot be reduced, it is irreducible or incarcerated, and a portion of the intestine may be bulging through the hernia sac. A hernia is strangulated if the intestine is trapped in the hernia pouch and the blood supply to the intestine is decreased. This is a surgical emergency and immediate treatment is needed.

The 3 types of Ventral Hernias are:

Epigastric (stomach area) hernia just below the breastbone to the navel/umbilicus (belly button).

Umbilical hernia: Occurs in the area of the belly button.

Incisional hernia. Develops at the site of a previous surgical incision or laparoscopic repair as a result of scar tissue or weakened muscles at the site.

Symptoms

The most common symptoms of a hernia are:

- Visible bulge in the abdominal wall, especially with coughing or straining
- Hernia site pain or pressure

Sharp abdominal pain and vomiting may mean that the intestine has slipped through the hernia sac and is strangulated. This is a surgical emergency and immediate treatment is needed.

Common Tests

History and Physical

The site is checked for a bulge.

Additional Tests (see Glossary)

Other tests may include:

- Ultrasound
- Computerized tomography (CT) scan
- Blood tests
- Urinalysis
- Electrocardiogram (ECG)—for patients over 45 or if high risk of heart problems
Keeping You Informed

Open versus Laparoscopic Incisional Repair
There is no one type of repair that is good for all ventral hernias. Laparoscopic repairs are associated with lower infection rates and shorter hospital stays. There is no difference in recurrence rates, long-term pain, or quality of life.

Will My Hernia Come Back?
Mesh reduces the risk that the hernia will return again. Absorbable mesh has been shown to decrease the risk the hernia will return and improves the quality of life. Mesh can be tacked, stapled, or sutured.

Obesity and wound complications increase the risk of recurrence. You may be placed on a weight loss, smoking cessation, or a diabetes control program before an elective repair to support the best outcome.

Surgical Treatment
The type of operation depends on the hernia size, location, and if it is a repeat hernia. Your health, age, anesthesia risk, and the surgeon’s expertise are also important. An operation is the only treatment for a hernia repair.

Open Hernia Repair
The surgeon makes an incision near the hernia site. The bulging tissue is gently pushed back into the abdomen. Sutures, or a tissue flap is used to close the muscle. With complex or large hernias, small drains may be placed going from inside to the outside of the abdomen. The site is closed using sutures, staples, or surgical glue.

Open Mesh Repair
The hernia sac is removed. Mesh is placed over the hernia site. Mesh is attached using sutures sewn into the stronger tissue surrounding the hernia site. Mesh is often used for large hernia repairs and may reduce the risk that the hernia will come back. The site is closed using sutures, staples, or surgical glue. The most basic approach is a primary open repair without mesh, used for defects of less than 2 cm.

Laparoscopic Hernia Repair
The surgeon will make several small punctures or incisions in the abdomen. Ports or trocars (hollow tubes) are inserted into the openings. Surgical tools are placed into the ports. The abdomen is inflated with carbon dioxide gas to make it easier for the surgeon to see the hernia. Mesh is sutured, stapled, or clipped to the muscle around the hernia site. The hernia site can also be sewn directly together.

Nonsurgical Treatment
Watchful waiting is an option for a hernia without symptoms. In a large study, 19% (1 in 5) of incisional hernias and 16% (1 in 7) of umbilical/epigastric hernias patients did watchful waiting. Four percent of those needed emergency surgery within 5 years. There were no differences in 30-day readmission, reoperation or death rates between patients who had surgery and patients who waited for hernia repair.

All patients should get treatment if they have sudden sharp abdominal pain and vomiting. These symptoms can indicate an incarcerated hernia and bowel obstruction. Trusses may help the comfort in about 1/3 of those who use them. Surgery is the only option to fix the hernia.
## Risks of this Procedure

### Risks Based on the ACS Risk Calculator in July, 2022*

*The ACS Surgical Risk Calculator estimates the risk of an unfavorable outcome. Data is from a large number of patients who had a surgical procedure similar to this one. If you are healthy with no health problems, your risks may be below average. If you smoke, are obese, or have other health conditions, then your risk may be higher. This information is not intended to replace the advice of a doctor or health care provider. To check your risks, go to the ACS Risk Calculator at [http://riskcalculator.facs.org](http://riskcalculator.facs.org).*
What You Can Expect

Home Medication
Bring a list of all of the medications, vitamins, and any over-the-counter medicines that you are taking. Your medications may have to be adjusted before your operation. Some medications can affect your recovery and response to anesthesia. Most often you will take your morning medication with a sip of water.

Anesthesia
Let your anesthesia provider know if you have allergies, neurologic disease (epilepsy, stroke), heart disease, stomach problems, lung disease (asthma, emphysema), endocrine disease (diabetes, thyroid conditions), or loose teeth; use alcohol or drugs; take any herbs or vitamins; or if you have a history of nausea and vomiting with anesthesia.

If you smoke, you should let your surgical team know, and you should plan to quit. Quitting before your surgery can decrease your rate of respiratory and wound complications and increase your chances of staying smoke-free for life. Resources to help you quit may be found at https://www.facs.org/for-patients/preparing-for-your-surgery/quit-smoking/

Length of Stay
If you have local anesthesia, you will usually go home the same day. You may stay overnight if you have a repair of a large or incarcerated hernia. A laparoscopic repair may result in a longer anesthesia time. Complications such as severe nausea and vomiting or an inability to pass urine may also result in a longer stay.

Safety Checks
An identification (ID) bracelet and allergy bracelet with your name and hospital/clinic number will be placed on your wrist. These should be checked by all health team members before they perform any procedures or give you medication. Your surgeon will mark and initial the operation site.

Fluids and Anesthesia
An intravenous line (IV) will be started to give you fluids and medication. For general anesthesia, you will be asleep and pain free during the operation. A tube may be placed down your throat to help you breathe during the operation. For spinal anesthesia, a small needle with medication will be placed in your back alongside your spinal column. You will be awake during the operation but pain-free.

The Day of Your Operation
- You will be told when to stop eating and drinking before your operation.
- You should bathe or shower and clean your abdomen with a mild antibacterial soap.
- You should brush your teeth and rinse your mouth with mouthwash.
- Do not shave the surgical site; the surgical team will clip the hair near the incision site.
- Let the surgical team know if you are not feeling well or if there have been any changes in your health since last seeing your surgeon.

What to Bring
- Insurance card and identification
- Advance directives (see glossary)
- List of medicines
- Loose-fitting, comfortable clothes
- Slip-on shoes that don’t require that you bend over

After Your Operation
You will be moved to a recovery room where your heart rate, breathing rate, oxygen saturation, blood pressure, and urine output will be closely watched. Be sure that all visitors wash their hands.

Preventing Pneumonia and Blood Clots
Movement and deep breathing after your operation can help prevent postoperative complications such as blood clots, fluid in your lungs, and pneumonia. Every hour, take 5 to 10 deep breaths and hold each breath for 3 to 5 seconds.

When you have an operation, you are at risk of getting blood clots because of not moving during anesthesia. The longer and more complicated your surgery, the greater the risk. This risk is decreased by getting up and walking 5 to 6 times per day, wearing special support stockings or compression boots on your legs, and for high-risk patients, taking a medication that thins your blood.

Questions to Ask

About my operation:
- What are the side effects and risks of anesthesia?
- What technique will be used to repair the hernia (laparoscopic or open; mesh or with sutures)?
- What are the risks of this procedure for me?
- Will you be performing the entire operation yourself?
- What level of pain should I expect and how will it be managed?
- How long will it be before I can return to my normal activities (work, driving, lifting)?
- May I have my hernia repaired during a gastric bypass surgery?
Your Recovery and Discharge

High-Fiber Foods
Foods high in fiber include beans, bran cereals and whole-grain breads, peas, dried fruit (figs, apricots, and dates), raspberries, blackberries, strawberries, sweet corn, broccoli, baked potatoes with skin, plums, pears, apples, greens, and nuts.

Thinking Clearly
If general anesthesia is given or if you need to take narcotics for pain, it may cause you to feel different for 2 or 3 days, have difficulty with memory, or feel more fatigued. You should not drive, drink alcohol, or make any big decisions for at least 2 days.

Nutrition
• When you wake up from the anesthesia, you will be able to drink small amounts of liquid. If you do not feel sick, you can begin eating regular foods.
• Continue to drink about 8 to 10 glasses of water each day.
• Eat a high-fiber diet so you don’t strain while having a bowel movement.

Activity
• Slowly increase your activity. Be sure to get up and walk every hour or so to prevent blood clot formation.
• You may go home the same day for a simple repair. If you have other health conditions or complications such as nausea, vomiting, bleeding, or infection after surgery, you may stay longer.
• Do not lift items heavier than 10 pounds or participate in strenuous activity for at least 6 weeks.

Bowel Movements
Avoid straining with bowel movements by increasing the fiber in your diet with high-fiber foods or over-the-counter medicines (like Metamucil® and FiberCon®). Be sure you are drinking 8 to 10 glasses of water each day.

When to Contact Your Surgeon
Contact your surgeon if you have:
• Pain that will not go away
• Pain that gets worse
• A fever of more than 101°F (38.3°C)
• Repeated vomiting
• Swelling, redness, bleeding, or foul-smelling drainage from your wound site
• Strong or continuous abdominal pain or swelling of your abdomen
• No bowel movement by 3 days after the operation

Handwashing
• If you have Steri-Strips in place, they will fall off in 7 to 10 days.
• If you have a glue-like covering over the incision, let the glue to flake off on its own.
• Avoid wearing tight or rough clothing. It may rub your incisions and make it harder for them to heal.
• Protect the new skin, especially from the sun. The sun can burn and cause darker scarring.
• Your scar will heal in about 4 to 6 weeks and will become softer and continue to fade over the next year.

Wound Care
• Always wash your hands before and after touching near your incision site.
• Do not soak in a bathtub until your stitches, Steri-Strips®, or staples are removed. You may take a shower after the second postoperative day unless you are told not to.
• Refer to the ACS Surgical Wound program at https://www.facs.org/for-patients/homeskills-for-patients/wound-management/
• A small amount of drainage from the incision is normal. If the dressing is soaked with blood, call your surgeon.

A gallon of milk weighs 9 pounds. Do not lift anything over 10 pounds.
### Pain Control

Your pain can be controlled using acetaminophen (Tylenol®) and ibuprofen (Motrin®, Advil®). Nonmedication therapies, such as ice may also be effective. For severe pain that is keeping you from moving and sleeping, an opioid may be needed. By day 4, most people report no severe pain after an operation. Pain from the surgical incision is usually gone in 7 to 10 days. See the Safe and Effective Pain Control Guide below or on the ACS website for more information. [https://www.facs.org/education/patient-education/safe-pain-control](https://www.facs.org/education/patient-education/safe-pain-control)

<table>
<thead>
<tr>
<th>Pain Description</th>
<th>What Can I Take to Feel Better</th>
<th>Most Common Therapies</th>

</thead>
</table>
| • I hardly notice my pain, and it does not interfere with my activities.  
• I notice my pain and it distracts me, but I can still do activities (sitting up, walking, standing). | Non-medication therapies  
+ Non-opioid, oral medications  
• Take as needed when you feel pain.  
• These help to decrease pain and swelling (inflammation) | Non-medication Therapies  
• Ice, elevation, rest, meditation, massage, distraction (music, TV, play) walking and mild exercise  
• Splinting the abdomen with pillows |
| • My pain is hard to ignore and is more noticeable even when I rest.  
• My pain interferes with my usual activities. | Non-Medication Therapy  
+ Non-opioid, oral medication  
Take these on a regular schedule | Take Non-opioid medication on a regular schedule instead of as needed. (Ex: Tylenol® every 6 hours at 9am, 3pm, 9pm, 3am and Motrin® every 6 hours and 12am, 6am, 12pm, 6pm |
| • I am focused on my pain, and I am not doing my daily activities.  
• I am groaning in pain, and I cannot sleep. I am unable to do anything.  
• My pain is as bad as it could be, and nothing else matters. | Non-Medication Therapy  
+ Non-opioid, oral medication  
Take these on a regular schedule | Opioids block pain and give a feeling of euphoria (feel high). Addiction, a serious side effect of opioids, is rare with short term use.  
Examples of short-acting opioids include: Tramadol (Ultram®), Hydrocodone (Norco®, Vicodin®), Hydromorphone (Dilaudid®) |

#### Keeping You Informed

**Pain after Ventral Hernia Repair**

Younger patients, females, those with preoperative pain or recurrent hernia may have pain at one month after surgery. At 1-month follow-up, more LVHR patients experienced pain and movement limitations. After 6 and 12 months there were no differences in quality of life. Length of stay and infection rates may be less in LVHR but overall complication and recurrence rates are equal.6
Electrocardiogram (ECG): a diagnostic test using a paper and a machine to record the electrical activity of the heart. The recording is called an electrocardiogram (ECG). The ECG shows how fast and regular the heart beats. It can help detect certain heart conditions, such as an extra heart beat, and damaged or weakened heart muscle.

Blood tests: Tests usually include a complete blood count (red blood cells, white blood cells, platelets, and hemoglobin) and tests to measure blood sugar, urea nitrogen, and creatinine. Other blood tests may include a blood chloride, carbon dioxide, blood urea nitrogen (BUN), and electrolytes profile, which measures sodium, potassium, calcium, and magnesium in the blood. Blood tests may also include liver function tests to check for or monitor the effects of conditions that affect the liver. Blood tests can also be performed to detect certain infections, such as HIV or hepatitis.

Advance directives: Documents signed by a competent person giving direction to health care providers about treatment choices.

Hematoma: A localized collection of blood in the tissue or organ.

Urinalysis: A visual and chemical examination of the urine, most often used to screen for urinary tract infections and kidney disease.

Nasogastric tube: A soft plastic tube inserted in the nose and down to the stomach; used to empty the stomach of contents and gases to rest the bowel.

Seroma: A collection of serous (clear/yellow) fluid.

Ultrasound: Sound waves are used to determine the location of deep structures in the body. A hand roller is placed on top of clear gel and rolled across the abdomen.

Local anesthesia: The loss of sensation only in the area of the body where an anesthetic drug is applied or injected.

General anesthesia: A treatment with certain medicines that puts you into a deep sleep so you do not feel pain during surgery.

Hernia: A collection of tissues, usually a pouch of muscle tissue in the abdomen, through which the intestines or other structures protrude. Hernias can be repaired surgically using mesh or other materials to reinforce the weakened area.

Urinary tract infection: An infection of the urinary system, including the kidneys, ureters, bladder, and urethra. Common symptoms include pain or burning when urinating, a strong urge to urinate, and having to urinate frequently. Urinary tract infections can be caused by bacteria, viruses, or other microorganisms.

Ventricular fibrillation: A type of abnormal heart rhythm in which the heart quivers instead of pumping blood. This can be caused by an injury to the heart, such as a heart attack, or by other conditions that increase the risk of death, such as a lung infection or a stroke. Ventricular fibrillation can be life-threatening and requires immediate medical attention.
