Pain Control .................................................7
Glossary/References .................................8

The Condition
Appendectomy is the surgical removal of the appendix. The operation is done to remove an infected appendix. An infected appendix, called appendicitis, can burst and release bacteria and stool into the abdomen.

What are the common symptoms?
- Abdominal pain that starts around the navel
- Not wanting to eat
- Low fever
- Nausea and sometimes vomiting
- Diarrhea or constipation

Treatment Options

Surgery
Laparoscopic appendectomy—The appendix is removed with instruments placed into small abdominal incisions.

Open appendectomy—The appendix is removed through an incision in the lower right abdomen.

Nonsurgical
Surgery is the standard treatment for an acute (sudden) infection of the appendix. Antibiotic treatment might be used as an alternative for specific patients and children.1,2

Benefits and Risks
An appendectomy will remove the infected organ and relieve pain. Once the appendix is removed, appendicitis will not happen again. The risk of not having surgery is the appendix can burst, resulting in an abdominal infection called peritonitis.

Possible complications include abscess, infection of the wound or abdomen, intestinal blockage, hernia at the incision, pneumonia, risk of premature delivery (if you are pregnant), and death.

Expectations

Before your operation—Evaluation usually includes blood work, urinalysis, and an abdominal CT scan, or abdominal ultrasound. Your surgeon and anesthesia provider will review your health history, medications, and options for pain control.

The day of your operation—You will not be allowed to eat or drink while you are being evaluated for an emergency appendectomy.

Your recovery—if you have no complications, you usually can go home 1 day after a laparoscopic or open procedure.

Call your surgeon if you are in severe pain, have stomach cramping, a high fever, odor or increased drainage from your incision, or no bowel movements for 3 days.
Keeping You Informed

**Appendicitis Pain**

Pain can be different for each person because the appendix can touch different organs. This can be confusing and make it difficult to diagnose appendicitis.

Most often pain starts around the navel and then moves to the right lower abdomen. The pain is often worse with walking or talking. During pregnancy, the appendix sits higher in the abdomen, so the pain may seem to come from the upper abdomen. In the elderly, symptoms are often not as noticeable because there is less swelling.4

**Other medical disorders have symptoms similar to appendicitis,** such as inflammatory bowel disease, pelvic inflammatory disease, gastroenteritis, urinary tract infection, right lower lobe pneumonia, Meckel’s diverticulum, intussusception, and constipation.

---

**The Appendix**

The appendix is a small pouch that hangs from the large intestine where the small and large intestine join. If the appendix becomes blocked and swollen, bacteria can grow in the pouch. The blocked opening can be from an illness, thick mucus, hard stool, or a tumor.

**Appendicitis**

Appendicitis is an infection of the appendix. The infection and swelling can decrease the blood supply to the wall of the appendix. This leads to tissue death, and the appendix can rupture or burst, causing bacteria and stool to release into the abdomen. This is called a ruptured appendix. A ruptured appendix can lead to peritonitis, which is an infection of your entire abdomen. Appendicitis most often affects people between the ages of 10 and 30 years old. It is a common reason for an operation in children, and it is the most common surgical emergency in pregnancy.3

**Appendectomy** is the surgical removal of the appendix.

---

**Symptoms**

- Stomach pain that usually starts around the navel and then moves to the lower right side of the abdomen
- Loss of appetite
- Low fever, usually below 100.3°F
- Nausea and sometimes vomiting
- Diarrhea or constipation

---

**Common Diagnostic Tests**

**History and Physical**

The focus will be on your abdominal pain. There is no single test to confirm appendicitis.3

**Tests (see glossary)**

- **Abdominal ultrasound or abdominal CT scan**—Checks for an enlarged appendix
- **Complete blood count (CBC)**—A blood test to check for infection
- **Rectal exam**—Checks for tenderness on the right side and for any rectal problems that could be causing the abdominal pain
- **Pelvic exam**—May be done in young women to check for pain from gynecological problems like pelvic inflammation or infection
- **Urinalysis**—Checks for an infection in your urine, which can cause abdominal pain
- **Electrocardiogram (ECG)**—Sometimes done in the older adult to make sure heart problems are not the cause of pain
Appendectomy

Surgical and Nonsurgical Treatment

**Surgical Treatment**

Acute appendicitis is an urgent problem requiring surgical consultation.

**Laparoscopic Appendectomy**

This technique is the most common for simple appendicitis. The surgeon will make 1 to 3 small incisions in the abdomen. A port (nozzle) is inserted into one of the slits, and carbon dioxide gas inflates the abdomen. This process allows the surgeon to see the appendix more easily. A laparoscope is inserted through another port. It looks like a telescope with a light and camera on the end so the surgeon can see inside the abdomen. Surgical instruments are placed in the other small openings and used to remove the appendix. The area is washed with sterile fluid to decrease the risk of further infection. The carbon dioxide comes out through the slits, and then the slits are closed with sutures or staples or covered with glue-like bandage or Steri-Strips. Your surgeon may start with a laparoscopic technique and need to change to an open technique. This change is done for your safety.4

**Open Appendectomy**

The surgeon makes an incision about 2 to 4 inches long in the lower right side of the abdomen. The appendix is removed from the intestine. The area is washed with sterile fluid to decrease the risk of further infection. A small drainage tube may be placed going from the inside to the outside of the abdomen. The drain is usually removed in the hospital. The wound is closed with absorbable sutures and covered with glue-like bandage or Steri-Strips.

**Nonsurgical Treatment**

If you only have some of the signs of appendicitis, your surgeon may treat you with antibiotics and watch for improvement. In an uncomplicated appendicitis, antibiotics may be effective, but there is a higher chance of reoccurrence.1,2,5

Keeping You Informed

**Laparoscopic versus Open**

For both adults and children, laparoscopic appendectomy has the advantage of lower infection rates, shorter hospital and recovery times, and lower pain scores.5

**Ruptured Appendix**

Unfortunately, many people do not know they have appendicitis until the appendix bursts. If this happens, it causes more serious problems. The incidence of ruptured appendix is 270 of 1,000 patients. This is higher in the very young and very old and also higher during pregnancy because the symptoms (nausea, vomiting, right-sided pain) may be similar to other pregnancy conditions.1,6

**Antibiotic Therapy**

In a comparison trial of 530 patients with confirmed appendicitis, 273 had their appendix removed. 257 patients were only treated with antibiotics. In the antibiotic group, 70 patients (27%) had a second episode within a year and needed an appendectomy.7
Risks of This Procedure

Your surgeon will do everything possible to minimize risks, but an appendectomy, like all operations, has risks.

<table>
<thead>
<tr>
<th>Risks of This Procedure from Outcomes Reported in the Last 10 Years of Literature</th>
<th>Percentage</th>
<th>Keeping You Informed</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intestinal obstruction: Short-term blockage of stool or fluids</td>
<td>3%</td>
<td>Swelling of the tissue around the intestine can stop stool and fluid from passing. You will be asked if you are passing gas, and bowel sounds will be checked. If you have a temporary block, a tube may be placed through your nose into your stomach for 1 or 2 days to remove fluid from your stomach.</td>
</tr>
<tr>
<td>Pregnancy risks</td>
<td></td>
<td>The risk of fetal loss increases to 10% when the appendix ruptures and there is peritonitis (infection of the abdominal cavity).6</td>
</tr>
<tr>
<td>Pediatric risks</td>
<td></td>
<td>Children with perforated appendix have increased wound infection rates and abdominal infections. There are no deaths reported with simple appendectomy.</td>
</tr>
</tbody>
</table>

<th>Risks of This Procedure Based on the ACS Risk Calculator in May 2017*</th>
<th>Percentage</th>
<th>Keeping You Informed</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wound Infection: Infection at the area of the incision</td>
<td></td>
<td>Antibiotics are typically given before the operation. Smoking can increase the risk of infection.</td>
</tr>
<tr>
<td>Return to the operating room</td>
<td></td>
<td>Significant pain and bleeding may cause a return to surgery.</td>
</tr>
<tr>
<td>Pneumonia: Infection in the lungs</td>
<td></td>
<td>Stopping smoking, walking, and deep breathing after your operation can help prevent lung infections.</td>
</tr>
<tr>
<td>Urinary tract infection: Infection of the bladder or kidneys</td>
<td></td>
<td>A urinary catheter (small thin tube) that drains urine from the bladder is sometimes inserted. Signs of a urinary tract infection include pain with urination, fever, and cloudy urine.</td>
</tr>
<tr>
<td>Blood clot: A clot in the legs that can travel to the lung</td>
<td></td>
<td>Longer surgery and bed rest increase the risk. Getting up, walking 5 to 6 times per day, and wearing support stockings reduce the risk.</td>
</tr>
<tr>
<td>Heart complication: Includes heart attack or sudden stopping of the heart</td>
<td></td>
<td>Problems with your heart or lungs can be sometimes be worsened by general anesthesia. Your anesthesia provider will take your history and suggest the best option for you.</td>
</tr>
<tr>
<td>Death</td>
<td></td>
<td>Death is extremely rare in healthy people.</td>
</tr>
<tr>
<td>Any complication, including: Surgical infections, breathing difficulties, blood clots, renal (kidney) complications, cardiac complications, and return to the operating room</td>
<td>Laparoscopic: 3.7% Open: 7.9%</td>
<td>Complications are higher in smokers, obese patients, and those with other diseases such as diabetes, heart failure, renal failure and lung disease. Wound healing may also be decreased in smokers.</td>
</tr>
<tr>
<td>Predicted length of stay</td>
<td></td>
<td>Laparoscopic ½ day; open 1.5 days.</td>
</tr>
</tbody>
</table>

*The ACS Surgical Risk Calculator estimates the risk of an unfavorable outcome. Data is from a large number of patients who had a surgical procedure similar to this one. If you are healthy with no health problems, your risks may be below average. If you smoke, are obese, or have other health conditions, then your risk may be higher. This information is not intended to replace the advice of a doctor or health care provider. To check your risks, go to the ACS Risk Calculator at http://riskcalculator.facs.org.
Appendectomy

Preventing Pneumonia and Blood Clots

Movement and deep breathing after your operation can help prevent postoperative complications such as blood clots, fluid in your lungs, and pneumonia. Every hour, take 5 to 10 deep breaths and hold each breath for 3 to 5 seconds.

When you have an operation, you are at risk of getting blood clots because of not moving during anesthesia. The longer and more complicated your surgery, the greater the risk. This risk is decreased by getting up and walking 5 to 6 times per day, wearing special support stockings or compression boots on your legs, and for high-risk patients, taking a medication that thins your blood.

Questions to Ask

About My Operation:

- What are the side effects and risks of anesthesia?
- What technique will be used to remove my appendix? Laparoscopic or open?
- What are the risks of this procedure for me?
- Will you be performing the entire operation yourself?
- What level of pain should I expect, and how will it be managed?
- How long will it be before I can return to my normal activities (work, driving, lifting)?
Your Recovery and Discharge

Keeping You Informed

High-Fiber Foods
Foods high in fiber include beans, bran cereals and whole-grain breads, peas, dried fruit (figs, apricots, and dates), raspberries, blackberries, strawberries, sweet corn, broccoli, baked potatoes with skin, plums, pears, apples, greens, and nuts.

Your Recovery and Discharge

Thinking Clearly
The anesthesia may cause you to feel different for 1 or 2 days. Do not drive, drink alcohol, or make any big decisions for at least 2 days.

Nutrition
- When you wake up, you will be able to drink small amounts of liquid. If you do not feel sick, you can begin eating regular foods.
- Continue to drink lots of fluids, usually about 8 to 10 glasses per day.
- Eat a high-fiber diet so you don’t strain during bowel movements.

Activity
- Slowly increase your activity. Be sure to get up and walk every hour or so to prevent blood clots.
- Do not lift or participate in strenuous activity for 3 to 5 days for laparoscopic and 10 to 14 days for open procedure.
- You may go home in 1 day. If your appendix ruptured or you have other health issues or complications, you may stay longer.
- It is normal to feel tired. You may need more sleep than usual.

Work and Return to School
- You can go back to work when you feel well enough. Discuss the timing with your surgeon.
- Children can usually go to school 1 week or less after an operation for an unruptured appendix and up to 2 weeks after a ruptured appendix.
- Most children will not return to gym class, sports, and climbing games for 2 to 4 weeks after the operation.

Bowel Movements
- After intestinal surgery, you may have loose watery stools for several days. If watery diarrhea lasts longer than 3 days, contact your surgeon.
- Pain medication (narcotics) can cause constipation. Increase the fiber in your diet with high-fiber foods if you are constipated. Your surgeon may also give you a prescription for a stool softener.

Pain
The amount of pain is different for each person. Some people need only 1 to 3 doses of pain control medication, while others need more.

Wound Care
- Always wash your hands before and after touching near your incision site.
- Do not soak in a bathtub until your stitches or Steri-Strips® are removed. You may take a shower after the second postoperative day unless you are told not to.
- Follow your surgeon’s instructions on when to change your bandages.

Handwashing Steri-Strips®
- A small amount of drainage from the incision is normal. If the drainage is thick and yellow or the site is red, you may have an infection, so call your surgeon.
- If you have a drain in one of your incisions, it will be taken out when the drainage stops.
- Steri-Strips will fall off in 7 to 10 days or they will be removed during your first office visit.
- If you have a glue-like covering over the incision, allow the glue to flake off on its own.
- Avoid wearing tight or rough clothing. It may rub your incisions and make it harder for them to heal.
- Protect the new skin, especially from the sun. The sun can burn and cause darker scarring.
- Your scar will heal in about 4 to 6 weeks and will become softer and continue to fade over the next year.
- Sensation around your incision will return in a few weeks or months.

Do not lift anything over 10 pounds.
A gallon of milk weighs 9 pounds.
**When to Contact Your Surgeon**

If you have:
- Pain that will not go away
- Pain that gets worse
- A fever of more than 101°F (38.3°C)
- Repeated vomiting
- Swelling, redness, bleeding, or bad-smelling drainage from your wound site
- Strong abdominal pain
- No bowel movement or unable to pass gas for 3 days
- Watery diarrhea lasting longer than 3 days

**Pain Control**

Everyone reacts to pain in a different way. A scale from 0 to 10 is often used to measure pain. At a “0,” you do not feel any pain. A “10” is the worst pain you have ever felt.

**Common Medicines to Control Pain**

**Narcotics** or opioids are used for severe pain. Possible side effects of narcotics are sleepiness; lowered blood pressure, heart rate, and breathing rate; skin rash and itching; constipation; nausea; and difficulty urinating. Some examples of narcotics include morphine, oxycodone (Percocet®/Percodan®), and hydromorphone (Dilaudid®). Medications are available to control many of the side effects of narcotics.

**Non-Narcotic Pain Medication**

Most non-opioid pain medications are nonsteroidal anti-inflammatory drugs (NSAIDs). They are used to treat mild pain and inflammation or combined with a narcotic to treat severe pain. Some side effects of NSAIDs are stomach upset, bleeding in the digestive tract, and fluid retention. These side effects usually are not seen with short-term use. Examples of NSAIDs include ibuprofen, Motrin®, Aleve®, and Toradol® (given as a shot).

**Non-Medicine Pain Control**

**Distraction** helps you focus on other activities instead of your pain. Music, games, and other engaging activities are especially helpful with children in mild pain.

**Splinting your stomach** by placing a pillow over your abdomen with firm pressure before coughing or movement can help reduce the pain.

**Guided imagery** helps you direct and control your emotions. Close your eyes and gently inhale and exhale. Picture yourself in the center of somewhere beautiful. Feel the beauty surrounding you and your emotions coming back to your control. You should feel calmer.

**Keeping You Informed**

Extreme pain puts extra stress on your body at a time when your body needs to focus on healing. Do not wait until your pain has reached a level “10” or is unbearable before telling your doctor or nurse. It is much easier to control pain before it becomes severe.

**Laparoscopic Pain**

Following a laparoscopic procedure, pain is sometimes felt in the shoulder. This is due to the gas inserted into your abdomen during the procedure. Moving and walking helps to decrease the gas and the right shoulder pain.

Thomas Whalen, MD, MMM, FACS
Marshall Schwartz, MD, FACS
Kathleen Heneghan, RN, MSN, CPN

GLOSSARY

Abdominal ultrasound: Sound waves are used to determine the location of deep structures in the body. A hand roller is placed on top of clear gel and rolled across the abdomen.

Abscess: Localized collection of pus.

Advance directives: Documents signed by a competent person giving direction to health care providers about treatment choices. They give you the chance to tell your feelings about health care decisions.

Adhesion: A fibrous band or scar tissue that causes internal organs to adhere or stick together.

Complete blood count (CBC): A blood test that measures red blood cells (RBCs) and white blood cells (WBCs). WBCs increase with inflammation. The normal range for WBCs is 8,000 to 12,000.

Computed tomography (CT) scan: A specialized X ray and computer that show a detailed, 3-D picture of your abdomen. A CT scan normally takes about 1½ to 2 hours.

Electrocardiogram (ECG): Measures the rate and regularity of heartbeats, the size of the heart chambers, and any damage to the heart.

Nasogastric tube: A soft plastic tube inserted in the nose and down to the stomach.

Urinalysis: A visual and chemical examination of urine, most often used to screen for urinary tract infections and kidney disease.
