The Condition
A hernia occurs when tissue bulges out through an opening in the muscles. Any part of the abdominal wall can weaken and develop a hernia, but the most common sites are the groin (inguinal), the navel (umbilical), and a previous surgical incision site.

Common Symptoms
- Visible bulge in the scrotum or groin area, especially with coughing or straining
- Burning or pressure at the hernia site

Benefits and Risks of Your Child’s Operation
Benefits—An operation is the only way to repair a hernia. Your child can return to normal activities in a short amount of time and, in most cases, will not have further discomfort.

Possible risks include—Return of the hernia; infection; injury to the bladder, blood vessels, intestines, or nerves; difficulty passing urine; continued pain and swelling of the testes or the groin area.

Risks of not having an operation—The hernia may cause pain and can increase in size. If the intestine becomes incarcerated (trapped) in the hernia pouch, there may be sudden pain, vomiting, and the need for an immediate operation. Strangulation may also cause reduced blood supply to the testes in boys and result in damage to the intestine.

Treatment Options
Surgical Procedure
Open hernia repair—An incision is made over the site and the hernia is repaired by suturing (sewing) the muscle closed.

Laparoscopic hernia repair—The hernia is repaired with instruments placed into small incisions in the abdomen.

Nonsurgical Procedure
An inguinal hernia will not go away on its own. Surgery is always recommended because of the high risk of the intestines getting caught in the hernia opening in young children. 1

Inguinal Hernia Location

Inguinal Hernia

Expectations
Before the operation—Evaluation may include blood work and urinalysis. Your child’s surgeon and anesthesia provider will discuss their health history, home medications, and options for pain control.

The day of the operation—Your child will not eat or drink for several hours before the operation (amount of time may depend on your child’s age). Check with the doctor’s office to see if your child should take their routine medication. A parent can usually stay with the child in the waiting area and recovery room.

Your child’s recovery—Your child may go home within 24 hours for small hernia procedures but may need to stay in the hospital longer for more complex repairs.

Call your Surgeon—If your child has severe pain, stomach cramping, chills, or a high fever (over 101°F or 38.3°C), odor or increased drainage from the incision, or no bowel movements for three days.
Recognizing Hernias in children

Inguinal hernias occur:
- In 5 of 100 full-term and 30 of 100 preterm infants
- 10 times more frequently in boys
- More frequently on the right (75%), less often on the left (25%), or on both sides of the groin (15%)  

Incarceration can occur in about 10% of pediatric inguinal hernias and increases to 30% in premature infants. Incarceration may result in severe complications if not repaired.

Other medical disorders that have symptoms similar to hernias include: enlarged lymph nodes, cysts, and testicular problems such as scrotal hydrocele.

The Condition

The Hernia

An **inguinal hernia** occurs when part of the intestine bulges through a gap near the groin. A **reducible hernia** can be pushed back into the opening. When intestine or abdominal tissue fills the hernia sac and cannot be pushed back, it is called **irreducible or incarcerated**. A hernia is **strangulated** if the intestine is trapped in the hernia pouch, and the blood supply to the intestine is decreased. **This is a surgical emergency.**

There are two types of **groin hernias**: Inguinal hernias are the most common type of all hernias. They appear as a bulge in the groin or scrotum and are more common in boys. A **Femoral hernia** appears as a bulge in the groin, upper thigh, or labia (skin folds surrounding the vaginal opening). A femoral hernia is more common in girls and is always repaired because of a high risk of strangulation.

Symptoms

The most common symptoms are:
- A bulge in the groin usually seen with straining or crying.
- There may be discomfort at the hernia site.
- Sharp abdominal pain and vomiting can mean that the intestine has slipped through the hernia sac and is **strangulated. This is a surgical emergency and immediate treatment is needed.**

Common Tests

**History and Physical exam**
The site is checked for a bulge.

Other tests may include **(see glossary)**:
- Digital finger exam
- Blood tests
- Urinalysis
- Ultrasound if the hernia is difficult to see or feel

**Open Hernia Repair**
The surgeon makes an incision above the hernia site, and the sac protruding through the gap in the muscles is repaired. An open repair can be done with local anesthesia. Pediatric repair is usually done as an open repair without mesh. If needed, orchidopexy (moving an undescended testicle down into the scrotum) will be performed with the hernia repair.
**Surgical and Nonsurgical Treatment**

**Inguinal Hernia**

The surgeon inserts small ports (hollow tubes) through punctures or small incisions in the abdomen. For children, the port is usually inserted through the umbilicus (belly button area). The abdomen is inflated with carbon dioxide gas to make it easier for the surgeon to see the internal organs. Surgical tools and a light are placed into the ports. The muscle at the hernia site is sutured together. The recurrence rate is the same as the open repair.11 Single-port laparoscopic procedures using the umbilicus as the only access site are gaining popularity in both pediatric and adult surgery.12

**Nonsurgical Treatment**

Watchful waiting is not recommended because of the high risk of incarceration, especially in young infants.1

**Symptoms**

- A bulge in the groin usually seen with straining or crying.
- There may be discomfort at the hernia site.
- Sharp abdominal pain and vomiting can mean that the intestine has slipped through the hernia sac and is strangulated. This is a surgical emergency and immediate treatment is needed.4

**Common Tests**

- History and Physical exam
- Digital finger exam
- Blood tests
- Urinalysis
- Ultrasound if the hernia is difficult to see or feel 1

**Keeping You Informed**

**Open vs. Laparoscopic repair**

The open suture (sewn) repair is done most often in young children. It is a short procedure and can be done with local anesthesia. Local anesthesia (pain and numbing medication) can be injected near the hernia site or provided in the back near the spine (caudal block or spinal anesthesia). Complications of the open approach are rare.13

The laparoscopic approach allows the surgeon to see the vas deferens and other important vessels easily, which may cause less trauma and injury and a quicker return to normal activity.5-14 The surgical incision size is reduced, and the other side of the groin can be inspected for a potential hernia.6 Laparoscopic repair usually requires general anesthesia and takes longer. Studies differ on the amount of pain and recurrence of the hernia in children when laparoscopy is compared with the open suture repair. A laparoscopic repair with mesh is not recommended until age 20 years due to a child’s continued growth and possible trauma to the vas deferens, which may result in infertility.
## Risks of this Procedure

<table>
<thead>
<tr>
<th>RISKS</th>
<th>WHAT CAN HAPPEN</th>
<th>KEEPING YOU INFORMED</th>
</tr>
</thead>
<tbody>
<tr>
<td>Long-term pain</td>
<td>Long-term groin pain following infant repair is rare. Groin pain was reported in 28 of 1,000 adults who had a hernia repair during childhood.</td>
<td>Pain is usually managed with acetaminophen or ibuprofen, and most children resume normal activity in a few days.</td>
</tr>
<tr>
<td>Recurrence (hernia comes back)</td>
<td>Pediatric inguinal hernia reoccurs with open repair in: 10 in 1,000 children who had a full term birth; 150 of 1,000 premature infant repairs and 200 of 1,000 repairs after incarceration. Recurrence following laparoscopic repair is 20 of 1000.</td>
<td>The majority of hernias recur within 5 years of repair. Laparoscopic repair is recommended for recurrent hernias because the surgeon avoids previous scar tissue.</td>
</tr>
<tr>
<td>Testicular atrophy (injury)</td>
<td>A strangulated or incarcerated hernia can result in a loss of blood supply to the testicles. This is reported as occurring on average in 30 per 1,000 cases and increases to 180 per 1,000 cases of emergency strangulation repairs.</td>
<td>Testicular atrophy is reported only in cases of strangulation and incarcereation. Unless the testes are necrotic, they should not be removed.</td>
</tr>
<tr>
<td>Testicular or scrotal pain/swelling</td>
<td>Fluid may accumulate in the scrotal sac (Hydrocele) after 12 of 1,000 surgeries.</td>
<td>Scrotal swelling after pediatric inguinal hernia repair usually resolves on its own.</td>
</tr>
<tr>
<td>Injury to the vas deferens</td>
<td>The vas deferens carries the sperm from the scrotal area to the penis. During hernia repair, it may be damaged. This may not be recognized until adulthood. It is reported to occur in less than 20 of 1,000 repairs.</td>
<td>Injury to the vas deferens during hernia repair in childhood may be a reason for infertility in men. Rare cases of infertility caused by the use of mesh have also surfaced.</td>
</tr>
<tr>
<td>Infection</td>
<td>Pediatric wound infection is reported as 12 of 1,000 patients.</td>
<td>Routine antibiotics are typically not given for inguinal or femoral hernia repair.</td>
</tr>
<tr>
<td>Iatrogenic (related to surgery) undescended testicle</td>
<td>Failure to replace the testicles back in the scrotum during hernia repair occurs in less than 10 in 1,000.</td>
<td>In males, the testicles move (descend) from the abdomen into the scrotum. In 40 of 1,000 full term infants and 300 of 1,000 premature infants the testicles remain in the abdomen. In about half of babies, the testicle descends into the scrotum by 6 months.</td>
</tr>
<tr>
<td>Injury to internal organs - bowel, bladder, blood vessels</td>
<td>Injury can be caused by instruments inserted with laparoscopic repair. Bowel/bladder injury is reported as less than 1 per 1,000 and blood vessel injury is less than 1 per 1,000.</td>
<td>For bladder injury, a Foley catheter remains in place to drain the urine until the bladder is healed. Rarely surgical repair is needed. For bowel injury, the bowel is repaired and/or a nasogastric tube is placed to keep the stomach empty. Any injury to a blood vessel is repaired.</td>
</tr>
<tr>
<td>Anesthesia</td>
<td>Most hernias are repaired on an outpatient basis. An overnight stay is usually indicated for full-term infants less than 3 months old. Local (spinal) anesthesia may be used in premature infants less than 36 weeks old.</td>
<td>Anesthesia complications are extremely rare. There is no difference in cardiac and respiratory problems between general and local anesthesia in premature infants. Children can expect to resume normal activity 48 hours after surgery.</td>
</tr>
<tr>
<td>Respiratory complications</td>
<td>Apnea (periods of not breathing) right after the operation is seen in 47 of 1,000 premature infants. Premature infants with large hernia repairs need help breathing from a machine (mechanical ventilation) in 340 of 1,000 cases.</td>
<td>Apnea is associated with premature infants who had a history of apnea and other medical problems prior to hernia repair. When large hernia contents are placed back in the abdomen of a premature infant, abdominal pressure on the lungs causes difficulty breathing.</td>
</tr>
<tr>
<td>Heart/cardiac complications</td>
<td>There are no reports of heart complications related specifically to a hernia operation.</td>
<td>Other health problems increase the risk for heart and anesthesia related complications. Your anesthesia provider will suggest the best anesthesia option for your child.</td>
</tr>
<tr>
<td>Death</td>
<td>No deaths are reported directly related to pediatric inguinal and femoral hernia repair.</td>
<td>The risks of complications and possible death are greater with strangulated and incarcerated hernia repairs.</td>
</tr>

Expectations: Preparing for Your Child’s Operation

Preventing Pneumonia and Blood Clots

Movement and deep breathing after the operation can help prevent postoperative complications such as blood clots, fluid in the lungs, and pneumonia.
Recovery and Discharge

Keeping You Informed

High-Fiber Foods
Foods high in fiber include beans, bran cereals and whole-grain breads, peas, dried fruit (figs, apricots, and dates), raspberries, blackberries, strawberries, sweet corn, broccoli, baked potatoes with skin, plums, pears, apples, greens, and nuts.

Thinking Clearly
If general anesthesia is given, it is not unusual for some children to feel upset and confused as anesthesia is wearing off. Your child may need more sleep than usual the first day home, and allowing them to wake naturally should help.

Nutrition
When your child wakes up from the anesthesia, they will be able to drink small amounts of liquid. If they do not feel sick, they can return to their regular diet.

Activity
• Your child will slowly increase their activity. They should get up and walk every hour or so to prevent breathing problems, pneumonia, and constipation.
• There is no lifting, climbing, or strenuous physical activity for several weeks following surgical repair of an inguinal hernia.
• Children can usually return to normal activities within a few days.

Return to School
After recovery, your child should be able to return to school or day care in 2 to 3 days.

Wound Care
• Always wash your hands before and after touching near the incision site.
• Your child may have Steri-strips over the incision site. These will fall off in 7 to 10 days. There may be a clear dressing over the Steri-strips which can usually be removed after 48 hours.
• Your child may shower or bathe after 2 days but avoid prolonged soaking.
• A small amount of drainage from the incision is normal. If the dressing is soaked with blood, call your surgeon.

Return to School
After recovery, your child should be able to return to school or day care in 2 to 3 days.

Bowel Movements
Avoid straining with bowel movements. Increasing the fiber in your child’s diet with high-fiber foods and drinking 8 to 10 glasses of fluid daily can help keep stools soft.

Pain
Most children have little to no pain after the repair of an inguinal hernia. Children’s acetaminophen (Tylenol), ibuprofen, or Tylenol with hydrocodone (Lortab elixir) can be used to relieve pain, with most children needing only 1 to 2 doses. Throat lozenges or popsicles for sore throat pain or dryness from the tube placed in the throat during anesthesia can also help.

When to Contact Your Child’s Surgeon
Contact your child’s surgeon if your child has:
• Pain that will not go away
• Pain that gets worse
• A fever of more than 101°F or 38.3°C
• Vomiting
• Swelling, redness, bleeding, or bad-smelling drainage from the wound site
• Strong or continuous abdominal pain or swelling of the abdomen
• No bowel movement 2 to 3 days after the operation

Handwashing Steri-strips
When to Contact Your Child’s Surgeon
Contact your child’s surgeon if your child has:
- Pain that will not go away
- Pain that gets worse
- A fever of more than 101°F or 38.3°C
- Vomiting
- Swelling, redness, bleeding, or bad-smelling drainage from the wound site
- Strong or continuous abdominal pain or swelling of the abdomen
- No bowel movement 2 to 3 days after the operation

Pain Control
Everyone reacts to pain in a different way. A pain scale will be used to measure your child’s pain. Extreme pain puts extra stress on the body at a time when the body needs to focus on healing.

Non-Narcotic Pain Medication
Most non-opioid analgesics are classified as non-steroidal anti-inflammatory drugs (NSAIDs). They are used to treat mild pain and inflammation or combined with narcotics to treat severe pain. Possible side effects of NSAIDs are stomach upset, bleeding in the digestive tract, and fluid retention. These side effects usually are not seen with short-term use. Let your doctor know if your child has allergies, diabetes, or any other conditions that might interact with pain medication.

Pain Control without Medicine
- **Distraction** will help your child focus on other activities instead of their pain. Reading to your child, playing quiet games, or other engaging activities can help them cope with mild pain and anxiety.
- **Imagery** will help your child think of other pleasant thoughts may also distract them from the pain or discomfort. Ask your child to close their eyes and imagine a beautiful place or feeling they have seen or experienced.

Glossary of Terms and More Information

For more information, please go to the American College of Surgeons Patient Education website at http://www.facs.org/patienteducation. For a complete review of hernia repair, consult Selected Readings in General Surgery, “Hernia” 2012 Vol. 37 No. 8 at www.facs.org/SGRS.

GLOSSARY

**Abdominal X ray:** Checks for any loops of bowel or air-filled sacs.

**Abdominal Ultrasound:** Sound waves are used to determine the location of deep structures in the body. A hand roller is placed on top of clear gel and rolled across the abdomen.

**Blood tests:** Tests may include a chemistry profile (sodium, potassium, chloride, carbon dioxide, blood urea nitrogen and creatinine) and complete blood count (red blood cell and white blood cell count).

**Computerized tomography (CT) scan:** A diagnostic test using X ray and a computer to create a detailed, three-dimensional picture of your abdomen or other area of the body.

**General anesthesia:** A treatment with certain medicines that puts you into a deep sleep so you do not feel pain during surgery.

**Incarceration:** The inability to reduce (push back) a protrusion of an organ or the fascia of an organ through the wall of the cavity that normally contains it.

**Local anesthesia:** The loss of sensation only in the area of the body where an anesthetic drug is applied or injected.

**Nasogastric tube:** A soft plastic tube inserted in the nose and down to the stomach; used to empty the stomach of contents and gases, to rest the bowel.

**Seroma:** A collection of serous (clear yellow) fluid.

**Strangulation:** Part of the intestine or fat is squeezed in the hernia sac, and blood supply to the tissue is cut off.

**Urinalysis:** A visual and chemical examination of the urine most often used to screen for urinary tract infections and kidney disease.

**DISCLAIMER**

This information is published to educate you about your specific surgical procedures. It is not intended to take the place of a discussion with a qualified surgeon who is familiar with your situation. It is important to remember that each individual is different, and the reasons and outcomes of any operation depend upon the patient’s individual condition.

The American College of Surgeons (ACS) is a scientific and educational organization that is dedicated to the ethical and competent practice of surgery; it was founded to raise the standards of surgical practice and to improve the quality of care for the surgical patient. The ACS has endeavored to present information for prospective surgical patients based on current scientific information; there is no warranty on the timeliness, accuracy, or usefulness of this content.
